I Foreword, introduction and data

Foreword

The Department of Food and Resource Economics (IFRO), University of Copenhagen, agreed with a funded contract (MFVM Id nr.: 2703310) to undertake an analysis regarding the consequences for the Danish fishery following the United Kingdom's (UK) decision to leave the European Union (EU) (in Danish: Analyse af konsekvenserne for fiskeriet ved Storbritanniens udtræden af EU).

The contract entered into force by the 1st January 2017 with finalisation in June 2017.

The following from IFRO has been a part of the work: Professor Peder Andersen, Associate Professor Jesper Levring Andersen, Senior Researcher Ayoe Hoff and Scientific Assistant Lisa Ståhl. Associate professor emeritus Hans Staby Frost has participated in discussions about the approach to modelling.

At the beginning of the project period, a meeting was held with The Danish Fishermen's Association, The Danish Pelagic Producers Organization, Marine Ingredients Denmark, and Danish Seafood Association.

Introduction

The government of the UK officially announced the 29th March 2017 that UK would follow the outcome of the referendum vote to leave the European Union. A process, also referred to as "Brexit", has been initiated implying that UK will not be a member of the European Union by April 2019.

Fisheries will be an important part of the Brexit EU negotiation process, not only because of its macroeconomic importance, but because of its status as a sector, which supports livelihoods in many regions and in regions with few alternative employment possibilities.

In order to get the best possible foundation for discussing how to divide fisheries in the future between the EU and UK, an array of aspects is relevant to have knowledge about beforehand.

The purpose of this report is to describe some of these aspects in form of the primary interactions between the Danish fishing sector and UK with focus on the following:

- 1) The activity of Danish fishing vessels in the UK Economic Exclusive Zone (EEZ)
- 2) The activity of fishing vessels from the UK in EU waters
- 3) Quota interactions between the Danish and UK authorities
- 4) Export and import of fish products between Denmark and UK

Other aspects could also become a part of and influence these discussions, including for instance market access, trade agreements and control and enforcement.

The first part of the report gives a picture of the importance of the access to UK fishing waters for the Danish fishing vessels and the importance of import and export of fish products for the Danish processing industry. Based on the description, the second part of the report estimates the potential economic consequences of Brexit for the Danish fisheries (including a regional focus), the processing industry (downstream services), and the onshore services (upstream services). The analyses are presented for different scenarios regarding Danish vessels' future quotas and access to UK fishing grounds.

Data, information and definitions

The present analysis is based on several data sources.

The Danish Agrifish Agency hosts several databases with detailed information about the activity undertaken by Danish vessels. By combining the information from the logbook, sales notes, and vessel registers, it is possible to provide a comprehensive description of which vessels conduct the activity of interest, what they do and where the vessels land. The descriptions cover landings in live weight as well as in value.

Furthermore, the cost structures of the relevant vessels are obtained from the Danish Account Statistics for Fishery provided by Statistics Denmark. A range of other information is also used and referred to in the text, when relevant.

When undertaking the description and analysis in the following, it is important to highlight the distinction between zones. Thus, when referring to the economic exclusive zone of UK, it is referred to as UK-EEZ. Following Brexit, the remaining member states in the European Union will have a reduced fishing area under their jurisdiction. This area will be called NEW-EU-EEZ.

In order to separate landings from the UK-EEZ and other zones, primarily NEW-EU-EEZ and Norwegian zone, the International Council for the Exploration of the Sea (ICES) statistical rectangles are used. A range of these rectangles will be overlapping between the UK-EEZ and other zones. In these cases, landings are distributed evenly between the UK-EEZ and the relevant other zones.

Maps showing the ICES statistical rectangles, subdivisions, economic exclusive zones and countries are included in Annex 1 and Annex 2.

II Description of the Danish and United Kingdom fishing sector and interactions between them

In order to provide a context and starting point for the analysis, the following section describes the Danish fishery sector's dependency on Danish fishing vessels' access to UK fishing grounds, quota exchanges, import/export of fishing products, including UK vessels' landings in Danish ports and the importance for the Danish processing industry and the onshore service industry.

Danish fishing vessels fishing in UK zone

The Danish fisheries' dependence on the UK-EEZ in recent years is described in the following section. Of the total landings by Danish vessels, 27-34 % of the value and 31-45 % of live weight came from the UK-EEZ for the period 2012-2016. It was primarily larger vessels which landed fish from the UK-EEZ. Depending on the year, between 66 and 85 vessels were active in the UK-EEZ. For these vessels, the average importance of the UK-EEZ ranged between 43-57 % of their total landings value and 43-63 % of their total live weight landings. Analysing the activity in the UK-EEZ in more detail, 33-43 vessels depended on this EEZ for more than 15 % of their total landings value. These "15%-vessels" landed 98 % of the total Danish value and live weight from the UK-EEZ. They caught mostly herring and mackerel and landed their catches primarily in Skagen, Hirtshals, Thyborøn, and Hanstholm. Minor shares were landed in UK harbours. The description in this report thus focuses on these 15%-vessels since they could potentially be the most impacted by Brexit.

As a starting point for the analysis of the fishing activity in the UK-EEZ, the number of vessels actually having activity in the zone is identified. Table II.1 below therefore shows on a yearly basis the number of Danish fishing vessels having fished in the UK-EEZ from 2012 to 2016. Vessels are included in the table no matter how much they land from the UK-EEZ. Thus in 2012, 85 vessels fished in the UK-EEZ, while in 2016 this number was reduced to 66 vessels and it was primarily large vessels above 24 meters.

Table II.1 Number of Danish fishing vessels fishing in UK-EEZ

	2012		2013		2014		2015		2016	
<12m	1	1%	1	1%	.	.

Source: The Danish Agrifish Agency Vessel Register, Logbook and Sales Notes Register 14th Feb. 2017.

For the years 2012-2016, table II.2 shows total yearly landings by Danish vessels, the landings by Danish vessels having fished in the UK-EEZ and the latter vessels' dependency on the UK-EEZ, the NEW-EU-EEZ, the Norwegian zone and other zones.

The importance of the UK-EEZ at the overall level for Danish fishery is that on average 29% of the landings value comes from fishing in this area, while it for live weight is 36%. In the period, 27-34% of the landings value comes from fishing in this area, while it for live weight is 31-45% with a reducing share.

Comparing the total landings by vessels having had landings from the UK-EEZ to these vessels' landings from that zone, the importance is on average 49% in the period, being between 43-57% of landings value. For landings in live weight, the importance of the UK-EEZ is 49% on average, being between 41-63% with the smallest shares in the most recent years.

Source: The Danish Agrifish Agency Vessel Register, Logbook and Sales Notes Register 14th Feb. 2017.

Having described the number of vessels fishing in the UK-EEZ and the overall dependency of the UK-EEZ for the Danish fishery, the next step is to focus on the vessels having high shares of landings from the UK-EEZ, and which will thus potentially experience substantial economic impacts, depending on the outcome of the Brexit negotiations.

In the following, the activity by vessels having more than 15% of their landings value from the UK-EEZ will therefore be described in detail. The 15%-vessels cover 98% of the total landings value from the UK-EEZ. The threshold of 15% is considered an appropriate level for concluding that if the accessibility to the UK-EEZ changes, it will negatively impact the economic performance of these vessels at a level which cannot directly be compensated via activity in other areas. Such compensation possibilities are considered more likely for the vessels below the 15%-dependency.

Table II.3 shows how many vessels have more than 15% of their total landings value in the UK-EEZ. Comparing to Table II.1, around 50% of the vessels fishing in the UK-EEZ fall under this threshold.

Table II.3 Number of Danish fishing vessels fishing in UK-EEZ with 15%-dependency

	2012		2013		2014		2015		2016	
18-24m	4	11%	5	12%	3	8%	3	7%	1	3%
24-40m	7	19%	10	23%	9	24%	10	24%	9	27%
>40m	25	68%	28	65%	25	68%	28	68%	23	70%

Source: The Danish Agrifish Agency Vessel Register, Logbook and Sales Notes Register 14th Feb. 2017.

Focusing only on these 15%-vessels of course implies that some landings from the UK-EEZ will not be included in the forthcoming analysis. Table II.4 displays the magnitude of this concentrated focus.

Table II.4 Landings distributed on UK-EEZ 15%-vessels and non-15%-vessels

Landings value (1,000 DKK)										
	2012		2013		2014		2015		2016	
Total UK-EEZ 15%-vessels	879,011	98%	999,671	98%	751,409	97%	887,162	97%	982,276	97%

Total	901,059	100%	1,015,158	100%	773,462	100%	910,904	100%	1,017,511	100%
Landings live weight (tonnes)										
	2012		2013		2014		2015		2016	
Total UK-EEZ 15%-vessels	195,645	98%	301,201	100%	231,264	97%	287,543	99%	200,759	96%
Total UK-EEZ non-15%-vessels	4,048	2%	1,267	0%	6,073	3%	4,095	1%	7,865	4%
Total	199,693	100%	302,468	100%	237,337	100%	291,638	100%	208,624	100%

Source: The Danish Agrifish Agency Vessel Register, Logbook and Sales Notes Register 14th Feb. 2017.

Thus, the 15%-vessels accounts for more than 96% of the value and live weight from UK-EEZ landings over the period.

Table II.5 shows the dependency of the UK-EEZ for the 15%-vessels. 53-71% of the landings value is from the UK-EEZ with smaller shares in the latest years, while 68-47% of the live weight landings is from the UK-EEZ also with smaller shares in years that are more recent. The 15 %-vessels' specific catches by species are shown in Table II.6 below.

Table II.5 Landings by the 15%-vessels distributed on zones

The composition of species caught in the UK-EEZ by the 15%-vessels is shown in Table II.6 together with their share of the vessels' landings from the UK-EEZ as shown in Table II.5. In this period, herring and mackerel are the most important species landed from the UK-EEZ. Sandeel is also important, but fluctuates between the years. The importance of demersal species such as cod and hake in the UK-EEZ, although important species in the Danish fishery in general, is low and varies over the years.

Table II.6 Landings of top 10 species in 2016 from the UK-EEZ by the 15%-vessels, measured by value, and share of total landings from the UK-EEZ by the 15%-vessels in table II.5

Given that the UK-EEZ covers a vast fishing area with different distances for the Danish vessels, Table II.7 shows which ICES subdivisions are the most important for the 15%-vessels. It is mainly North Sea fishing areas, which are important to these vessels.

Table II.7 Landings distributed on ICES subdivisions by the 15%-vessels

Note: See Annex 2 for geographical location of the ICES-subdivisions.

Four Danish harbours receive landings of fish from the UK-EEZ by the 15%-vessels as shown in Table II.8. Skagen receives the most of these landings, more than three times the amount landed in Hanstholm. Herring is the primary species landed in Skagen together with some species for reduction used for the production of fishmeal and oil (sandeel and blue whiting). Herring and mackerel are the most important species in Hirtshals, species for reduction, a bit of herring and minor amounts of demersal species are landed in Thyborøn, while landings of demersal species primarily occur in Hanstholm.

The 15%-vessels also land some of their landings in UK harbours, cf. Table II.9. A minor amount of landings caught in other zones than the UK-EEZ is landed in UK harbours. Overall, the share of landings in UK harbours is low and between 2-9 % of value and 0-6 % of live weight.

Below, Table II.10 displays which UK harbours receive the landings, while Table II.11 shows which species are landed. The largest shares are landed in Lerwick and Peterhead, while the most landed species are mackerel and herring. As seen in Table II.11, the share of mackerel and herring landings by 15%-vessels in UK harbours is small compared to the total landings by these vessels.

Fishing in the ICES statistical rectangles divided between the UK-EEZ and NEW-EU-EEZ

The International Council for the Exploration of the Seas (ICES) has for statistical analysis standardized the division of sea areas into statistical rectangles measuring 30 times 30 nautical miles each. These rectangles have been used to divide the fishery activity between the UK-EEZ and NEW-EU-EEZ. However, in some circumstances a statistical rectangle cannot solely be allocated to the UK-EEZ or NEW-EU-EEZ. In this analysis, the fishing activity in these statistical rectangles has been divided to the UK-EEZ and NEW-EU-EEZ based on how much of the area is in each of these EEZs.

It can be argued that the fishery in these boarder rectangles takes place with some coincidence. It is thus relevant to consider how much fishing actually takes place within the divided rectangles. Table II.12 shows the distribution of landings value between the UK-EZZ and NEW-EU-EEZ for the divided rectangles, including the species caught.

Table II.12 Landings value divided between UK-EEZ and NEW-EU-EEZ within divided rectangles by the 15%-vessels (1,000 DKK)

	UK-EEZ					NEW-EU-EEZ				
	2012	2013	2014	2015	2016	2012	2013	2014	2015	2016

Total from EEZ	879,011	999,671	751,409	887,162	982,276	205,662	271,247	352,331	581,338	394,190

Source: The Danish Agrifish Agency Vessel Register, Logbook and Sales Notes Register 14th Feb. 2017.

In comparison to the total landings value, the landings value originating from the divided rectangles in the UK-EEZ and NEW-EU-EEZ respectively accounts for approximately 13% of the total landings value on average. Given the magnitude of the fishing activity in the divided rectangles, and the possible coincidence of this fishery, makes it relevant to consider in the analysis to come, what the impacts are if the landings from the UK-EEZ divided rectangles can be caught in the NEW-EU-EEZ instead.

Danish quota exchanges with UK

Every year, Denmark undertakes a range of quota exchanges with other countries, including the UK. There are several reasons for undertaking these exchanges. Generally, the countries involved must be expected to obtain a benefit from making an exchange. However, the actual background for the exchange can be driven by a range of reasons.

One reason for an exchange could be that the quotas are based on historical catch patterns. Therefore, the quotas are not adjusted to account for the actual situation for the individual countries. Thus, it happens regularly that a country ends up in a situation, in which some quotas are constraining and others are not. Therefore, in order to continue fishing, exchanges are made with countries, where this constraint is not a problem.

Another reason for exchanges could be better use of the various countries' fleet technology and activity distribution. Thus, instead of moving vessels around, it might be better to concentrate the activity in certain areas. This reduces expenses in relation to transportation time, but also the costs of shifting gear, if necessary.

In Table II.13, the total numbers of Danish quota exchanges in the period from 2012 to 2016 are shown, including the number specifically with UK. During the period, around 25% of all the Danish quota exchanges are made with UK, peaking in 2016.

Table II.13 Danish quota exchanges

	2012	2013	2014	2015	2016
Total number of quota exchanges with UK	23	33	31	30	47
Total number of quota exchanges overall	120	135	131	127	148
Share of UK exchanges (%)	19	24	24	24	32

Source: The Danish Agrifish Agency and the Fishery Data Exchange System (FIDES)-database.

The total Danish quotas by the end of the year for the period 2012-2016 were on average a bit below 900,000 tonnes. Measured in live weight, Table II.14 shows how much Denmark has transferred to other countries in total and to the UK specifically. On average, 9% of the transfers from Denmark have been to the UK, while the transfers from the UK to Denmark on average amount to 15%.

Table II.14 Danish quota exchanges in live weight (1,000 tonnes)

	2012	2013	2014	2015	2016	Total
Transfers from DK to UK	3,827	9,186	12,956	7,551	14,257	47,777

Transfers from UK to DK	3,056	9,412	15,294	13,650	22,911	64,322
Total transfers to DK	65,228	98,763	103,872	84,249	84,549	436,661
Share of UK transfers (%)	5	10	15	16	27	15

Source: The Danish Agrifish Agency and the Fishery Data Exchange System (FIDES)-database.

Table II.15 and Table II.16 provide a more detailed view of the 10 most transferred quotas between Denmark and UK and vice versa. Measured in live weight, mackerel quota is the most transferred species, followed by sprat, where Denmark receives a larger amount than handed over to the UK. However, most of the transfers are in packages including several quotas, which are not necessarily the same. For instance, sprat is not necessarily exchanged with sprat, but with other quotas.

Table II.15 Danish quota transfers to the UK, 10 most important species in live weight (1,000 tonnes)

Throughout the years, Denmark and the UK have exchanged quotas frequently. On many occasions, their fishing fleets operate in the same waters (primarily the North Sea), and this gives a range of reasons for exchanging quotas. At the overall level, Denmark receives more quota from the UK than vice versa, measured in live weight. However, despite mackerel being the most exchanged quota, many of the exchanges are for quotas of low value species primarily for reduction (sprat, horse mackerel, sandeel). Not being able to undertake such quota exchanges in the future can have an economic impact for the 15%-vessels especially, because these most exchanged species are also the most important species for their fishery.

Quota exchanges with the UK are to this extent important, given that on average, 9% of the Danish transfers goes to the UK, while 15% of the transfers to Denmark come from UK. However, the primary part of the exchanges is undertaken for species which are also primarily caught in the UK-EEZ. Thus, the future importance of exchanges for these species will to a high degree depend on the possibility for Danish vessels to fish in the UK-EEZ at all.

Having described the fishing activities taking place in relation to Danish and UK vessels, fishing area, and harbour interactions, the following sections describe the imports and exports of fish and fish products to and from Denmark in relation to the UK. Although this information does not feed into the economic analysis in the following chapter, it provides further contexts of the amounts and values of fish and fish products moving between the two countries.

Imports of fish to Denmark

In 2011-2015, Denmark on average imported 1,185 thousand tonnes of fish at a value of DKK 15.5 billion. By quantity, the most imported fish products were reduction species, fishmeal/oil, and whole saltwater fish. By value, the most important products were prepared/conserved products and whole saltwater fish. Of the fish imports to Denmark, 3 % of both quantity and value was imported from the UK, corresponding to 37 thousand tonnes with a value of 457 million DKK.

The total value of Danish fish imports was on average 15.5 billion DKK in the period 2011-2015. Of this, prepared or conserved fish made up 20% on average, followed by whole saltwater fish which made up 19% of the total import value, see Table II.17 (The Danish Agrifish Agency, 2017a).

Considering import quantities in Table II.17 below, total Danish imports were on average 1,185 tonnes in the years 2011-2015. Reduction fish made up the largest part (37%), followed by fishmeal, oil, etc. (19%), and whole saltwater fish (19%) (The Danish Agrifish Agency, 2017a).

Table II.18 below show the value and quantity of Danish fish imports from the UK, based on The Danish Agrifish Agency (2017a). As seen in the table, of the total imports of fish to Denmark, fish from the UK made up 3% of the import value and quantity in 2011-2015.

The table also shows the imports of different categories of fish to Denmark from the UK. Denmark imported 37 thousand tonnes of fish from the UK on average in the years 2011-2015 with an average value of 457 million DKK. It is seen that in terms of both value and quantity, whole saltwater fish is the most imported fish category from the UK to Denmark. The import of whole saltwater fish from the UK had an average yearly value of 188 million DKK in the same time period. This corresponds to 6% of the total Danish imports of whole saltwater fish and 1.2% of overall fish imports to Denmark

in 2011-2015. Denmark imported on average 19 thousand tonnes whole saltwater fish yearly in 2011-2015. Whole saltwater fish from the UK thereby made up on average 9% of the total whole saltwater fish imports to Denmark and 1.6% of the total fish imports to Denmark in the years 2011-2015. Mackerel was also imported in the form of filets and in prepared/conserved form. Mackerel filets from the UK made up around half of imports of mackerel filets to Denmark and 0.1 % of the overall import value (The Danish Agrifish Agency, 2017a).

Table II.18 Denmark's import of fish from the UK, 2011-2015, and % of overall Danish imports of fish type (as shown in Table II.17)

Table II.19 provides a more detailed overview of the saltwater fish category from the UK to Denmark. Whole UK mackerel make up the majority of imports of whole mackerel to Denmark. This import represents on average 66% of the total import value of whole mackerel to Denmark in the years 2011-2015 and 0.7% of the overall Danish fish imports. In terms of quantities, whole mackerel from the UK make up on average 70% of the total, whole, mackerel quantity imported to Denmark in 2011-2015 and 1.0% of the overall Danish fish imports. Besides as whole fish, mackerel was also imported as filet or as prepared/conserved mackerel products (The Danish Agrifish Agency, 2017a).

Of the overall imported quantities of fish products to Denmark of 1,185 thousand tonnes on average, the main type of fish products imported to Denmark were reduction fish, fishmeal/oil, and whole saltwater fish in 2011-2015. The total import value was 15.5 billion DKK on average. The most important fish imports by value were prepared/conserved fish products followed by whole saltwater fish. In this time period, Denmark imported on average 37 thousand tonnes of fish and fish products from the UK with an average value of 457 million DKK. The import to Denmark from the UK consisted primarily of whole saltwater fish. This quantity represented 9% of the total import of whole saltwater fish to Denmark and 6% of the value of imported whole saltwater fish on average. Of the overall import value and quantity to Denmark, the import of whole saltwater fish from the UK represented 1.2 and 2 % on average respectively. Of whole saltwater fish imported from the UK, mackerel was the most important one, making up 70% of the total imported quantity of whole mackerel to Denmark and 65% of the value of whole mackerel imports. Besides as whole fish, mackerel was also imported as filet or as prepared/conserved mackerel products. Other important whole saltwater fish from the UK in terms of quantity were herring, saithe, and cod while in terms of value they were cod, saithe, and herring (The Danish AgriFish Agency, 2017a).

Exports of fish from Denmark

In 2011-2015, Denmark on average exported 993 thousand tonnes of fish and fish products with a value of 21.5 billion DKK. Of this, 9 % of the quantity and 8 % of the value was exported to the UK. This corresponded to 87 thousand tonnes with a value of 1.7 billion DKK. By value, it was primarily fish in the form of prepared/conserved products, fishmeal/oil and whole saltwater fish that were important fish exports to the UK.

As seen in Table II.20 below (The Danish Agrifish Agency, 2017a), Denmark's export of fish had an average yearly value of 21.5 billion DKK in the period 2011-2015. The categories of fish products most important in terms of value were prepared/conserved fish, whole saltwater fish, and fishmeal/oil with average fish export value shares of 20%, 20%, and 16% respectively. The average yearly volume exported from Denmark was 993 thousand tonnes. The most important fish categories in terms of quantity were fishmeal/oil, whole saltwater fish, and prepared/conserved fish with average export quantity shares of 34%, 27% and 11%, respectively (The Danish Agrifish Agency, 2017a).

Source: The Danish AgriFish Agency database February 24th 2017(The Danish AgriFish Agency, 2017a)

Table II.21 below provides an overview of Danish fish exports to the UK in 2011-2015. The value of fish products exported from Denmark to the UK was 1.7 billion DKK on average per year, while the exported quantity was 87 thousand tonnes on average. Fish exports to the UK thus represented 8% of the total Danish fish exports in terms of value and 9% in terms of volume.

In relation to the total exports from Denmark to the UK, prepared/conserved fish was the most important followed by fishmeal/oil and saltwater fish, both in terms of value and quantity (The Danish Agrifish Agency, 2017a). Exports of prepared/conserved shrimp to the UK made up 23% of the total Danish export value of prepared/conserved shrimp products and 2.1% of the total Danish fish export value, while prepared/conserved mackerel products to the UK made up 43% of the total Danish export value of prepared/conserved mackerel products and 0.8% of the total fish export value. In the 'whole saltwater fish' category, haddock and mackerel made up the largest parts. Exports of whole haddock to the UK thus made up both 58 % of export value and quantity of Danish haddock exports while it corresponded to 0.4 % of the total Danish fish export value. Whole mackerel to the UK corresponded to 23 % of the Danish export value of whole mackerel and 0.3 % of the value of the total Danish fish exports (The Danish Agrifish Agency, 2017a).

When comparing overall imports and exports, Danish exports to the UK were on average in 2011-2015 about 2 times larger than imports from the UK in terms of quantity and almost 4 times higher in terms of value. Mackerel was primarily imported from the UK in the form of whole mackerels and to a lesser extent as filets and prepared/conserved products. About two-thirds of the mackerel export to the UK was whole mackerel and about a third was prepared/conserved mackerel.

Table II.21 Denmark's export of fish to the UK, 2011-2015, and % of total Danish fish exports (as shown in Table II.20)

Source: The Danish AgriFish Agency database February 24th 2017 (The Danish AgriFish Agency, 2017a)

In summary, Denmark on average exported 993 thousand tonnes of fish and fish products at a value of 21.5 billion DKK yearly in 2011-2015. The most exported fish products in terms of quantity were fishmeal/oil, whole saltwater fish, and prepared/conserved fish. The most important fish exports in terms of quantity were prepared/conserved fish, whole saltwater fish, and fishmeal/oil (The Danish AgriFish Agency, 2017a).

Exports from Denmark to the UK were in the same time period on average 87 thousand tonnes at a value of 1.7 billion DKK. This corresponds to 9% of the total Danish fish exports in terms of quantity and 8% in terms of value. The most important export to the UK in terms of quantity was fishmeal/oil, whole saltwater fish, and prepared/conserved fish. In terms of value, the most important exports to the UK were prepared/conserved fish, fishmeal/oil and whole saltwater fish exports from Denmark to the UK were about 2 times larger than imports from the UK in terms of quantity and almost 4 times higher in terms of value. (The Danish AgriFish Agency, 2017a).

Landings in Denmark

In Table II.22, the total yearly landing quantities and values in Danish harbours during 2011-2015 are shown. The average yearly landings in 2011-2015 in Denmark, regardless of fishing grounds, were 889 thousand tonnes in live weight with a landings value of 3.4 billion DKK (The Danish AgriFish Agency, 2017b).

On average, UK vessels landed 27 thousand tonnes live weight in Danish harbours per year, corresponding to an average of 3% of the total live weight landed in Denmark. The value of UK vessels' landings in Denmark was on average 156 million DKK yearly in 2011-2015 corresponding to 5% of the overall average landings in Danish harbours in that period (The Danish AgriFish Agency, 2017b). From a technical perspective, these are statistically also registered as import, while Danish vessels' landings in UK harbours are registered as Danish exports.

Considering the fish species landed by UK vessels in Danish harbours, mackerel make up the largest proportion during the period in terms of quantity with 10 thousand tonnes live weight landed yearly on average with a value of 70 million DKK on average in 2011-2015. On average, these make up 39% of the landed quantities by UK vessels in Denmark. After mackerel, blue whiting and herring was the most landed species in terms of quantity (The Danish AgriFish Agency, 2017b).

Table II.22 All vessels' and UK's vessels landings in Denmark, average 2011-2015 and UK vessels' landings of top 3 species by quantity

	2011	2012	2013	2014	2015	Average 2011-2015

Geographic distribution of UK landings in Denmark

According to The Danish AgriFish Agency (2017b), and as seen above, UK vessels landed on average 27 thousand tonnes of fish worth 156 million DKK in Danish harbours yearly in 2011-2015. In this period, 2015 showed the highest value of landed fish while the largest amounts were landed in 2014, cf. Table II.23. Throughout the period, Hirtshals has seen the largest landings of fish by UK vessels, both in terms of value and volume. The value of landings in Hirtshals represented 56% of the total average landings by UK vessels in Denmark in 2011-2015. The volumes landed in Hirtshals

represented 41% of the total landings by UK vessels. Hanstholm is the second most important harbour for UK vessels landing in Denmark in the period (The Danish AgriFish Agency, 2017b). As seen above, the landings by 15%-vessels in Denmark mostly take place in Skagen and Hirtshals. The volumes landed by UK vessels in Danish harbours are in 2012 and 2013 about the same level as the volumes landed by the 15%-vessels in UK harbours. In 2014 and 2015, UK vessels landed about 3 and 9 times more in Danish harbours than the 15%-vessels landed in UK harbours.

Landings by UK and EU vessels from UK-EEZ

Below, Table II.25 shows the yearly landings from the UK-EEZ as estimated by Napier (2016). According to Napier (2016a), the estimated total landings originating from waters in the UK-EEZ was 1.1 million tonnes per year in 2012-2014 with a value of 8.6 billion DKK. Landings by EU vessels (without the UK) in the UK-EEZ were estimated to be 58% of all landings by weight and 43% of the landings value, corresponding to 650 thousand tonnes and 3.7 billion DKK. Landings by UK vessels were an estimated 42% of the landings weight and 57% of landings value on average per year in the same period, corresponding to 476 thousand tonnes and almost 5 billion DKK (Napier, 2016).

Table II.24 Estimated average yearly landings 2012-2014 from the UK-EEZ by area

	UK vessels				EU vessels (excl. UK)				Total			
	Landings (1,000 tonnes)		Value (1,000 DKK*)		Landings (1,000 tonnes)		Value (1,000 DKK*)		Landings (1,000 tonnes)		Value (1,000 DKK*)	
ICES area 4	260	55%	2,459,700	50%	412	63%	1,648,910	44%	671	60%	4,108,610	48%
ICES area 6	136	29%	1,402,940	28%	117	18%	747,020	20%	254	23%	2,149,960	25%
ICES area 7	79	17%	1,047,650	21%	116	18%	1,275,400	34%	195	17%	2,323,050	27%

Note: Due to rounding, the totals column may differ from totals of UK and EU vessels

Note: See Annex 2 for geographical location of the ICES-subdivisions.

Source: Napier (2016)

In the meantime, Napier (2017) estimated UK vessels' average yearly landings in 2011-2015 for landings from the Northeast Atlantic, which represented 98 % of total UK landings (Napier, 2017). These estimates are from a more recent report and are averages for a larger time range. The UK's total landings from the UK-EEZ are therefore not directly comparable to the ones in Table II.24 above. In the Northeast Atlantic, UK vessels on average caught 647 thousand tonnes per year in 2011-2015 with a value of approximately 7.2 billion DKK. Of these, the large majority (81 %), corresponding to 527 thousand tonnes, was caught within the UK-EEZ, and 14% of UK vessels' landings, corresponding to 92 thousand tonnes, were caught in the EU-EEZ outside the UK (Napier, 2017).

According to Napier (2017) the UK's landings of demersal species from the Northeast Atlantic made up an estimated 158 thousand tonnes of which 18%, corresponding to almost 28 thousand tonnes, was caught in EU waters outside the UK-EEZ. Further, the UK's landings of pelagic species have been estimated to 332 thousand tonnes. 16% of these landings, corresponding to 53 thousand tonnes, were caught in EU waters outside the UK-EEZ. Furthermore, the UK vessels' landings of reduction fish species were estimated to be on average 11 thousand tonnes per year with 90 % being landed from the UK-EEZ (Napier, 2017).

Table II.25 Estimated average yearly landings by UK vessels, average 2011-2015

	Landings (1,000 tonnes)		Value (1,000 DKK*)	
Total UK vessels landings	647	100%	7,166,837	100%
Landings from UK-EEZ	527	81%	5,875,039	82%
Landings from EU-waters excl. UK-EEZ	92	14%	997,545	14%
Landings from outside EU	28	4%	294,253	4%

Source: Napier (2017)

To sum up, the total landings in Denmark were on average 889 thousand tonnes yearly between 2011-2015 with a value of 3.4 billion DKK. UK vessels landed 27 thousand tonnes in Denmark on average per year with a value of 156 million DKK. This corresponded to 3% of the landed quantity in

Denmark and 5% of the landed value. The most landed species were mackerel, blue whiting, and herring. On average in 2011-2015, UK vessels landed the largest quantities in Hirtshals, followed by Skagen, Thyborøn, and Hanstholm. In terms of value, the largest values were landed in Hirtshals, followed by Hanstholm, Skagen, and Thyborøn (The Danish AgriFish Agency, 2017b).

Yearly landings in the UK-EEZ in 2012-2014 were estimated by Napier (2016) to an average of 1,127 thousand tonnes with a value of 8.6 billion DKK. Of these, UK vessels landed 42% of the landed quantity and 57% of the landing value. EU vessels, which were not from the UK, landed 58% of the quantities and 43% of the value (Napier 2016).

UK vessels landed most of their catch, 81% of the quantity, from waters in the UK-EEZ, while a smaller proportion (14%) was landed from EU waters outside the UK-EEZ (Napier, 2017).

The fish processing industry in Denmark

Nielsen (2016) provides an assessment of the economic situation of the fish processing industry in Denmark in recent years, both overall and by fish processing segment. On this basis of this, this section provides an overview of the processing industry and the role of processing herring and mackerel and fishmeal. Table II.26 below provides a summary of the relevant numbers in the text.

There were 103 fish processing companies in 2013 accounting for 3,019 full time positions. The number of companies processing herring and mackerel was nine with 426 full time positions. There were five fishmeal factories employing 356 full time positions (Nielsen, 2016).

The total production in the processing industry was 449,356 tonnes of fish and shellfish in 2015. Excluding reduction species, the total production of fish and fish products for consumption was 167,605 tonnes. Of this, herring represented almost 30% and mackerel almost 7%. The production by the companies processing herring and mackerel was almost 58,000 tonnes, which corresponded to 34% of the production of fish for consumption (169,995 tonnes) and 13% of the total production (449,361 tonnes incl. production by fishmeal companies). Fishmeal factories produced 279,361 tonnes, representing 62% of the total (Nielsen, 2016).

In 2013, herring and mackerel processing companies' gross revenue of 1,575 million DKK represented 11% of the processing industry's total gross revenue of 14,071 million DKK, incl. the production of fishmeal. With 4,469 million DKK in gross revenue, fishmeal represented 32% of the total. Of the total revenue excl. fishmeal, herring and mackerel processing represented 9,062 million DKK corresponding to 16% (Nielsen, 2016).

The industry's total costs were 12,381 million DKK in 2013, of which herring and mackerel processing companies made up almost 10% with 1,224 million DKK in costs. Fishmeal production made up 35% of the costs with 4,348 million DKK. Excluding fishmeal production, the costs were 8,033 million DKK, of which the herring and mackerel companies represented 15% (Nielsen, 2016).

The large majority of the total industry's earnings were made by processing companies dealing with fish products for consumption. Here, the earnings were 1,569 million DKK in 2013, compared to the

total earnings of 1,690 million DKK, including the production of fishmeal. Fishmeal factories had 121 million DKK in earnings, corresponding to 7% of the total earnings. Herring and mackerel processing had earnings of 350 million DKK, representing almost 22% of total earnings in the whole processing industry and 22% of the consumption processing earnings (Nielsen, 2016).

The net profits of the processing industry were 335 million DKK in 2013. The companies processing fish for consumption had net profits of 458 million DKK, of which herring and mackerel represented 23% with 106 million DKK in earnings. Companies producing fishmeal had negative profits of 122 million DKK in 2013, although being positive in 2012 and 2011 (Nielsen, 2016).

Table II.26 Overview of the fish processing industry in Denmark in 2013 or 2015 and herring and mackerel as well as fishmeal's relative part

	Unit	Value
Total no. of companies, 2013		103

- fishmeal		-122

Source: Nielsen (2016)

The Danish processing industry employed 3,019 full time positions in 2013, of which 426 were employed by companies processing herring and mackerel. The industry as whole produced about 450 thousand tonnes in 2015. Of this, 167 thousand tonnes were for consumption purposes of which herring represented almost 30%. About a third of the production for consumption was made up by herring and mackerel while these species made up 13% of the overall production in the processing industry. The production of fishmeal made up 62% of the total production by the processing industry (Nielsen, 2016).

The gross revenue of the industry as a whole was 14 billion DKK in 2013, of which herring and mackerel companies represented 11% and fishmeal companies 32%. Earnings were 1.7 billion DKK of which companies processing fish for consumption made up the large majority with 1.6 billion DKK. Earnings by companies processing fishmeal and oil were 121 million DKK. Net profits for the whole industry were 335 million DKK. Companies processing herring and mackerel had net profits

of 106 million DKK while companies processing fishmeal and oil had negative profits of 122 million DKK in 2013, although being positive in 2011 and 2012 (Nielsen, 2016).

Onshore service industry

Besides the processing industry, the fishery generates activity in the local harbours and communities not just through the income they generate to the crew, which they then use for private consumption in the local town or region, but also through buying supplies, maintaining the vessels and gears etc.

A reduced activity level in the fishery will necessarily result in a reduced level of activity for shipyards, oil bunkers, gear producers, provision suppliers etc. Depending on the level of this activity reduction, some of these industries will be flexible enough to either reduce their cost level or find alternative ways of counteracting these developments. Unfortunately, no data is available for the onshore service industry, which in isolation shows the importance of the fishing activity in contrast to their other activities.

However, a few indicators are available in order to reflect where the economic impact on the onshore service industry will most likely happen.

The first indicator is the homeport of each vessel. A vessel will most likely undertake some of their onshore services in their homeport in form of repairs and various supplies. Table II.27 shows the homeport for the 15%-vessels have. Thyborøn is homeport for around 50% of all these vessels, while the remaining ports are primarily Skagen, Esbjerg, Hanstholm and Hirtshals. Thus, it will be the onshore service industry on the west coast part of Northern Jutland that are expected to be affected the most following the Brexit, but the magnitude is dependent on the likely outcome of the negotiations.

Table II.27 Number of 15%-vessels distributed by homeport

Homeport	2012	2013	2014	2015	2016
Skagen	5	6	5	6	3
Østerby, Læsø		1	1		
Frederikshavn		1	1		
Grenå		1	1	2	
Esbjerg	4	4	4	4	4
Hvide Sande	2	1	1		
Thyborøn	16	18	15	20	16
Hanstholm	2	4	3	2	4
Hirtshals	7	6	5	6	5
Christiansø	1	1	1	1	1
Total	37	43	37	41	33

Source: The Danish Agrifish Agency Vessel Register and Sales Notes Register 14th February 2017.

Although a vessel does not always land its landings in its homeport, the distribution of total landings value on homeport gives some added information compared to the distribution of vessels by homeport. For instance, it is observed from Table II.28 that a larger share of the total landings value

of the 15%-vessels is by vessels with homeport in Skagen. This thus indicates that these vessels have larger activity on average, and the onshore service industry will therefore expectedly be impacted higher than what was noted from Table II.27.

Table II.28 Landings value of 15%-vessels distributed by homeport (1,000 DKK)

Homeport	2012	2013	2014	2015	2016
Skagen	251,284	145,602	223,022	472,028	421,877

Source: The Danish Agrifish Agency Vessel Register and Sales Notes Register 14th February 2017.

Furthermore, the total landings value can be used as indicator for the crew payments, and thus be used as a proxy for the effects on private consumption, if it is assumed that the crew lives in the area around the homeport of the vessel they work on.

III Analysis and results

Scenarios

Depending on the expected outcome of the Brexit negotiations between EU and UK, various scenarios can be relevant to analyse. However, at the time of this analysis there are no indications of the negotiation range, and the analysis is therefore based on assumptions about a few potential outcomes.

The consequences for Danish vessels will for instance be influenced by the level of access to the UK-EEZ, the quotas available and the possibility for vessels to reallocate their activity from the UK-EEZ to the NEW-EU-EEZ.

To determine some boundaries for the expected outcome and to assess the consequences of Brexit, two stylized/limiting scenarios with clear and transparent assumptions will be used to set the boundaries of the possible outcome for Danish fisheries of Brexit:

- 1) The negotiations end up with unchanged access to the UK-EEZ, i.e. a continuation of the current CFP (i.e. quota distribution, technical rules, capacity restrictions etc.) and a baseline for the following scenarios.
- 2) All Danish (and other EU) vessels are excluded from fishing in the UK-EEZ, without possibility to take some of the catches previously taken in UK-EEZ in the NEW-EU-EEZ after Brexit.

The UK-EEZ and NEW-EU-EEZ does not strictly follow the ICES-rectangles, thus some of the current fishing activity takes place in rectangles, which in the future will be divided between UK and EU. In the scenarios above, the fishery is allocated to each part of the divided rectangle based on the geographical size of the rectangles belonging to UK and EU. A third scenario, lying between scenario 1 and scenario 2 will therefore consider the potential effects of assuming that the landings from these divided rectangles can still be caught. Thus, it is in scenario 3 assumed that:

- 3) As in scenario 2, all Danish (and other EU) vessels are excluded from fishing in the purely UK-EEZ rectangles but the fishing activity taking place in the UK part of the divided rectangles can take place in the NEW-EU-EEZ, assuming this geographical move of fishing effort in itself does not imply additional costs.

Building on top of the latter scenario, a fourth scenario is defined.

- 4) Catches taken in UK-EEZ before Brexit can to a varying degree be caught in the NEW-EU-EEZ, depending on historical catch patterns of the different species.

A basic assumption is that vessels' current allocation of their activity is based on economic considerations about where to obtain the highest profit. If the Danish fishing vessels are excluded from the UK-EEZ, their future behaviour and thus fishing activity will be based on the possibility to obtain a profit from fishing in another area, where they are allowed to fish. The vessels will

reallocate their fishing effort to the best available alternative. Their considerations in relation to such a decision are based on the availability of fish and quota, the landings value, and the costs related to undertake this change in activity. If the value of the landings is below the operating costs (variable costs), fishing will be stopped. However, no matter where and how much they eventually decide to fish, this will give rise to a lower profit than when they fished in the previous UK-EEZ zone.

It is of central importance to consider whether it is possible to catch the fish previously caught in UK-EEZ in a new area, i.e. the question asked in scenario 4. For instance, is it possible to catch the entire or parts of the current mackerel landings from the UK-EEZ in the NEW-EU-EEZ? And if so, is it profitable?

Optimally, this type of analysis makes use of very detailed information about the biological situation and possibilities in different areas, together with earnings and costs information in order to determine in which new areas it will be economically attractive to fish, if it is no longer possible to fish in the UK-EEZ. However, such detailed information on especially the biological side is not available, and it has therefore been necessary to approach the analysis in a more simplistic and stylized way, as explained in detail below.

Approach to analysis

The analysis is based on data covering 2014, 2015 and 2016. These three years are considered to be representative for the situation in the Danish fishery leading up to Brexit negotiations regarding fishing rights, with regard to negative as well as positive fluctuations in quotas, prices, and costs between various years.

The calculation is static-comparative and addresses the question of what would have happened in each of the three years in each of the considered scenarios, if Brexit had been in place in those years. The model is thus not a dynamic model, which is able to account for changed fishing behaviour, stock developments, fleet adjustments, price changes in landings and costs etc. Thus, the analysis is not a prediction of the future situation since this would require knowledge on future stock abundance, quotas, prices, costs, and behavioural changes.

Distribution of landings weight, landings value, and fishing effort is obtained from the databases of the Danish Agrifish Agency covering information at vessel and trip level for the Danish fishery. Cost information, based on a representative sample of the Danish fishing fleet, is obtained from Statistics Denmark, covering the years 2014 and 2015, while costs for 2016 are estimated using the data for previous years.

Given that the earnings and cost information from Statistics Denmark represent an average vessel within a specific fleet, it is necessary to adjust these to reflect the earnings and costs of the vessels fishing specifically in the UK-EEZ. From the Agrifish Agency database, average earnings are available for the vessels fishing in the UK-EEZ zone, and assuming the same proportional distribution, relative to earnings, of the various cost components for these vessels as the average Danish vessel, costs for

the UK-EEZ vessels are adjusted with the proportion between their earnings and the earnings of an average Danish vessel.

The cost components are divided into variable and fixed costs. Of the former, fuel costs and costs for provisions and ice/chilled sea water are considered dependent on the number of days at sea, while sales costs and crew payments are dependent on the landings value. Fixed costs cover insurance costs, maintenance costs, various other costs, and capital costs. These are all considered to be fixed and independent on the level of activity. As such, these costs can only be avoided if the vessel is scrapped (which can potentially also come with a cost, if the scrap value is lower than the remaining debt in the vessel) or sold.

Thus, in scenarios 2-4, where the activity is lower than in scenario 1 where nothing is changed, the costs for fuel, provisions, and ice is reduced proportionally with the reduction in number of days at sea, while sales costs and crew payments are reduced proportionally with the reduction in landings value. However, the fixed costs are not reduced as the number of vessels is assumed constant in each year.

In scenario 2, the fishing effort previously used strictly in UK-EEZ, including the part of UK-EEZ lying on the UK side of the divided rectangles is assumed not to be applied elsewhere. Thus, the only fishing effort applied is the effort previously applied in the NEW-EU-EEZ, leading to a reduction in landings value (relative to scenario 1). In this situation, the landing values only include the previously obtained landings values in the NEW-EU-EEZ. Variable costs are reduced according to the reduction in effort.

In scenario 3, it is assumed that the effort previously applied on the UK side in the dividing rectangles is still applied and the corresponding landings values previously obtained on the UK side of the dividing rectangles are still obtained. In rectangles on the UK side outside the dividing rectangles no effort is applied, and this effort is not moved to the NEW-EU-EEZ. Thus, effort and the obtained landings value are slightly higher than in scenario 2, and the costs are adjusted accordingly.

In scenario 4, which builds upon scenario 3, the focus is on the up to five economically most important species caught in the UK-EEZ by each of the fleets in 2014-2016, and on to which degree the fraction of these species previously caught in UK-EEZ outside the dividing rectangles can be caught in NEW-EU-EEZ. A number of assumptions are applied when asking this question:

- 1) Catches of a given species can only be moved within an ICES area, i.e. if a fleet has caught herring in the UK-EEZ part of ICES area 4A, it is assumed that this herring catch can only be taken in the NEW-EU-EEZ part of ICES area 4A, and not in any other areas.
- 2) There is only the possibility for a given fleet to move catches of a given species from the UK-EEZ part of an ICES area to the NEW-EU-EEZ part of the ICES area, if the fleet has previously caught that species in the NEW-EU-EEZ part of the ICES area. I.e. relating to the example given in point 1 above, it is only allowed that the herring previously caught in the UK part of area 4A is caught in the NEW-EU-EEZ part of 4A, if scenario 1 shows that the fleet has caught herring in this area.

- 3) For a species previously caught in UK-EEZ, the effort needed in NEW-EU-EEZ to take this catch (or part of it) is based on historical catch per effort in NEW-EU-EEZ of this species. I.e. if the historical catches per effort of a given species is lower in NEW-EU-EEZ than it was in UK-EEZ it will demand more effort, and thus cost more to catch this species in NEW-EU-EEZ.
- 4) The effort used to catch a given species in NEW-EU-EEZ must not exceed the effort used to catch that species in UK-EEZ. This assumption is made to avoid that any fleet suddenly operates beyond what is physically possible when moving catches. Thus, if the effort needed to catch a given species is higher in NEW-EU-EEZ than in UK-EEZ, only the effort originally applied in UK-EEZ to catch the species will be applied, and less will be caught in NEW-EU-EEZ, although at the same cost.
- 5) If the historical catch of a given species taken by a given fleet in the NEW-EU-EEZ part an ICES area is less than 5% of the historical catch of that species taken by the fleet in the UK-EEZ part of the ICES area, it is assumed that it is not possible to move any of the catch taken in the UK-EEZ part of that area. Thus, it is assumed that if a given species is taken mainly in UK-EEZ, then the catch taken in the NEW-EU-EEZ is accidental and/or noise in catch recordings, and that it is therefore unrealistic that the UK-EEZ part of the catch can be taken elsewhere.
- 6) If the historical catch of a given species taken by a given fleet in the NEW-EU-EEZ part of an ICES area is between 5% and 25% of the historical catch of that species taken by the fleet in the UK-EEZ part of the ICES area, it is assumed that the maximum amount of that species that can be moved is equal to the amount previously taken in NEW-EU-EEZ. As in point 5, this assumption is made to avoid that the calculations predict an unrealistic large catch of a given species in NEW-EU-EEZ, compared with historical catch patterns.
- 7) When the historical catch of a given species taken by a given fleet in the NEW-EU-EEZ part of an ICES area is above 25% of the historical catch of that species taken by the fleet in the UK-EEZ part of the ICES area, the catch of that species moved from the UK-EEZ to the NEW-EU-EEZ part of the ICES area is evaluated using points 1-4 above.

Given these assumptions, scenario 4 will build further onto scenario 3 by analysing the economic consequences, if the entire or parts of the catches previously taken in UK-EEZ can be taken in NEW-EU-EEZ following the assumptions described above.

Table III.1 below shows the up to five economically most important species taken by each fleet in UK-EEZ during the period 2014-2016. The number of species varies between the fleets depending on their fishing pattern in the UK-EEZ. For instance for Danish seine 18-24m, plaice is the by far most important species caught in the UK-EEZ, while five species are to a varying degree economically very important for the reduction trawlers above 40m.

Table III.1 Key species from the UK-EEZ based on landing value

		Species #1	Species #2	Species #3	Species #4	Species #5
18-24m	Danish seine	Plaice				
24-40m	Trawl reduction Trawl consumption	Norway pout Cod	Sandeel Hake	Monk	Saithe	
>40m	Purse seine Trawl reduction Trawl mixed	Herring Herring Sandeel	Mackerel Mackerel Norway pout	Sandeel Sandeel Herring	Blue whiting Sprat	Horse mac.

Note: Reduction vessels are vessels, where at least 80% of their yearly landings value consist of reduction species,
Consumption vessels are vessels, where at least 80% of their yearly landings value consist of species for human consumption,
Mixed vessels are vessels in between the above.

Within scenario 4, a sub-scenario will be analysed for each key species individually and furthermore a sub-scenario assuming that the landings of all these key species can be moved to the NEW-EU-EEZ.

With this array of scenarios, it is possible to address a range of potential outcomes following Brexit. The results are of course dependent on the assumptions made, but they are informative for further discussion and potential analysis.

The analysis is solely undertaken for the active 15%-vessels, i.e. vessels having caught at least 15% of the landings value in the UK-EEZ in a year and still active by the end of the year. As described in Section I, these vessels undertake almost the entire Danish fishery in the UK-EEZ.

Economic effects for the fishing fleets

This section will present and comment on the economic (financial) effects for the fishing fleets obtained from each scenario described above. The first part will focus on scenario 1-3, while scenario 4 and the accompanied sub-scenarios are addressed afterwards.

The presentation will focus on three economic measures:

- 1) Landings value
- 2) Gross profit defined as landings value minus operating (variable) costs
- 3) Net profit defined as gross profit minus crew payments

Gross profit provides a measure for profit, which is left to pay for labour and capital, and the net profits illustrate the amount left to pay for capital and any excess payments to the owner.

Each table will show the outcomes of each measure as a three-year average for 2014-2016, but more detailed information is provided in the annexes referred in each table. The tables include the total value for each fleet as well as the average value per vessel.

The development in landings value in scenario 1 to 3 is shown in Table III.2. In scenario 1, the total landings value 2014-16 would have been 1.4 billion DKK with the current CFP. In the case that Danish vessels are not allowed to fish in the UK-EEZ, the total landings value would be reduced by 57% to

0.6 billion DKK. Assuming that the landings from the shared ICES-squares can be caught in the NEW-EU-EEZ, this implies a reduction of 50% compared to scenario 1.

It is especially the vessels above 40m which are affected. These vessels catch large volumes of mackerel and herring in the UK-EEZ. The Danish seines' landings values are reduced significantly due to large landings of plaice caught in the English Channel, but a lot of this is caught in divided ICES-squares, thus in scenario 3, the reduction is only 12%.

Table III.2 Landings value 2014-16-average for scenario 1-3 (1,000 DKK)

			Scenario 1	Scenario 2		Scenario 3	
			Given the current CFP	No landings from UK-EEZ		Landings from shared ICES-squares between UK-EEZ and NEW-EU-EEZ	
Total	18-24m	Danish seine	5,232	1,949	-63%	4,425	-15%
	24-40m	Trawl reduction	39,022	20,182	-48%	22,700	-42%
		Trawl consumption	138,217	90,187	-35%	107,036	-23%
	>40m	Purse seine	372,858	127,311	-66%	153,102	-59%
		Trawl reduction	215,666	149,840	-31%	157,883	-27%
		Trawl mixed	633,245	211,789	-67%	256,654	-59%
	Total			1,404,240	601,258	-57%	701,800
	18-24m	Danish seine	2,346	739	-69%	2,061	-12%
	24-40m	Trawl reduction	11,535	6,101	-47%	6,801	-41%
		Trawl consumption	22,488	14,880	-34%	17,558	-22%
	>40m	Purse seine	103,860	35,012	-66%	42,074	-59%
		Trawl reduction	16,255	11,226	-31%	11,836	-27%
		Trawl mixed	69,748	23,382	-66%	28,369	-59%

Note: Please see Annex 3 for a detailed table

The effects on gross profits are shown in Table III.3 below. Gross profit is thus also reduced despite that some of the activity reduction will imply lower variable costs. Total gross profit in scenario 1 is 956 million DKK, reduced to 243 million DKK in scenario 2 and in scenario 3, it is 328 million DKK in total.

At the vessel level, gross profit is in scenario 2 reduced by more than 80% for the mixed trawlers above 40m and reduction trawlers 24-40m. In scenario 3, purse seiners above 40m together with the two fleets previously mentioned see a reduction in gross profit above 70%. The amounts left to handle expenditures for labour and capital is thereby reduced considerably.

Table III.3 Gross profit 2014-16-average for scenario 1-3 (1,000 DKK)

			Scenario 1	Scenario 2		Scenario 3	
			Given the current CFP	No landings from UK-EEZ		Landings from shared ICES-squares between UK-EEZ and NEW-EU-EEZ	
Total	18-24m	Danish seine	2,584	90	-97%	1,977	-23%
	24-40m	Trawl reduction	17,391	3,037	-83%	4,880	-72%
		Trawl consumption	82,664	45,487	-45%	58,608	-29%
	>40m	Purse seine	291,567	66,517	-77%	89,626	-69%
		Trawl reduction	94,335	43,531	-54%	49,578	-47%

Note: Please see Annex 4 for a detailed table

After having settled the payments to the crew, net profits show what is left to pay the invested capital and any extra payments to the owners. Table III.4 shows that in scenario 2, net profit is in total reduced by 82% from 700 million DKK to 127 million DKK. All fleets are influenced significantly, and despite that scenario 3 shows a small improvement compared to scenario 2, the reduction is still 72%.

Table III.4 Net profit 2014-16 -average for scenario 1-3 (1,000 DKK)

			Scenario 1	Scenario 2		Scenario 3	
			Given the current CFP	No landings from UK-EEZ		Landings from shared ICES-squares between UK-EEZ and NEW-EU-EEZ	
Total	18-24m	Danish seine	695	-612	-188%	377	-46%

Note: Please see Annex 5 for a detailed table

Turning to scenario 4 and its sub-scenarios, Table III.5 gives a summary of the aggregated economic effect of scenarios 1-3 and the version of sub-scenario 4, where increased landings of all of the up to five most important species in the UK-EEZ for each fleet is assumed to take place. In these sub-scenarios 4, it is assumed that more effort than previously used in the UK-EEZ cannot be applied in the NEW-EU-EEZ and that landings from the NEW-EU-EEZ cannot be higher than the landings previously obtained in the UK-EEZ, given the assumptions previously described.

Thus, given the assumptions about the possibility and restrictions to transfer landings from UK-EEZ to NEW-EU-EEZ for all top 5-species will naturally result in an improved economic situation for the fishery compared to scenario 2 and scenario 3, but it is still far from scenario 1.

Table III.5 Aggregated landings value, gross profit and net profit, average of 2014-16 -scenario 1-3 and scenario 4 with increased landings of top-5 species (1,000 DKK)

	Scenario 1	Scenario 2		Scenario 3		Scenario 4	
	Given the current CFP	No landings from UK-EEZ		Landings from shared ICES-squares between UK-EEZ and NEW-EU-EEZ		All landings of top 5 species transferred from UK-EEZ to NEW-EU-EEZ, if possible	
Landings value	1,404,240	601,258	-57%	701,800	-50%	772,963	-45%
Gross profit	956,039	243,502	-75%	328,175	-66%	386,711	-60%
Net profit	699,750	127,063	-82%	192,546	-72%	238,824	-66%

In order to describe which species contribute the most to the improvement in the economic measures, Table III.6, Table III.7, and Table III.8 show detailed economic effects of allowing increased landings of the up to five most important species in the UK-EEZ for each fleet.

Take for instance the landings value in Table III.6 for purse seiners, where three important species are identified. The analysis shows that it is primarily transfers of mackerel which increases the landings value, while sandeel and herring increases landings value to a minor extent. Furthermore, the figures for purse seiners show that given the assumptions made, the landings value is still only around half of the level in scenario 1.

For some of the species, no change is observed at all, for instance Trawl reduction 24-40m and Norway pout. Specifically, for this example, the no change result is due to the fact that despite that Norway Pout is caught in 4A of the NEW-EU-EEZ, the amounts are so small that it is not considered possible to transfer any of the amounts caught in 4A UK-EEZ, cf. assumption 5. Other factors could be that the species caught in the UK-EEZ is not caught at all in the corresponding ICES-subdivision in the NEW-EU-EEZ.

Economic effects for the processing sector

For the processing industry, the future possible supplies from the fleet are of key interest. Large reductions will most likely result in changes in the production capacity, unless other suppliers can be attracted, for instance from UK vessels catching species which Danish vessels previously have caught.

The total supplies landed in various Danish harbours, harbours in UK (UK) and harbours not located in either Denmark or UK (xDKUK) for the four scenarios are presented in Table III.9 for reduction species, Table III.10 for pelagic consumption species and Table III.11 for demersal consumption species.

Large potential reductions in the supply of the reduction species (blue whiting and sandeel) and the pelagic consumption species (mackerel and herring) are observed, but only minor changes for sprat. However, the figures also indicate that some of the reduced landings in Danish harbours of mackerel and herring could potentially be offset by attracting landings of these species currently landed in UK harbours or other foreign harbours.

Table III.9 Total supplies of reduction species to harbours 2014-16-average (tonnes)

Species	Harbour	Scenario 1 Given the current CFP	Scenario 2 No landings from UK-EEZ	Scenario 3 Landings from shared areas	Scenario 4 Transferred landings

Note: Please see Annex 7 for a detailed table

xDKUK refers to landings in harbours not located in Denmark or UK

UK refers to landings in harbours located in UK

IV Summary and perspectives

The decision by the UK about leaving the European Union causes a range of negotiations about the future collaboration between the remaining EU Member States and the UK. Fisheries are one of the areas that will be a part of these negotiations.

Importance of the UK-EEZ to Danish fisheries

Overall, the Danish fisheries obtained a substantial part of its landings from the UK Exclusive Economic zone (UK-EEZ) in 2012-2016, cf. Table IV.1 below. The volume of landings from the UK-EEZ has varied between 200-300 thousand tonnes, with a landings value between 0.7-1.0 billion DKK. Given that the total landings by Danish vessels has been between 500-875 thousand tonnes, corresponding to a value of 2.9-3.4 billion DKK, the landings from the UK-EEZ thus correspond to 27-34% of Danish landings value and 31-45% of landings measured in live weight.

Table IV.1 Landings by Danish vessels, their dependency on UK-EEZ and UK-EEZ active vessels' landings on areas

Source: The Danish Agrifish Agency Vessel Register, Logbook and Sales Notes Register 14th February 2017.

In total, 66 vessels fished in the UK-EEZ in 2016, but only 33 of these had more than 15% of their landings value from the UK-EEZ. However, these vessels (named 15%-vessels) are the larger Danish fishing vessels and are primarily above 24 meters in overall length. The 15%-vessels land 98% of both landings value and weight from the UK-EEZ, and the analysis therefore focuses on these vessels.

The most important species for these vessels in the UK-EEZ are herring and mackerel, while sandeel and other species for reduction (fish meal and oil) in some years also are important species. They primarily catch these species in the North Sea, but the fishing waters west of Scotland has become of increasing importance. The vessels mainly land their catches in Skagen, Hirtshals, Thyborøn, and Hanstholm, while landings in UK harbours are around 5% out of the total landings made by the 15%-vessels.

In 2011-2015, UK vessels' landings in Denmark corresponded to on average 3 % of total landings weight in Denmark and 5% of the total landings value while the most landed species were mackerel, blue whiting, and herring. Of the landings by UK vessels in Denmark, most of the catch was landed in Hirtshals and Hanstholm.

In the same period, import of fish and fish products from the UK constituted 3 % of Danish fish import value as well as quantity on average. The export of fish and fish products to the UK was 8 % of the total Danish fish exports by value and 9% by quantity.

The processing industry in Denmark consisted of 103 companies and employed 3,019 full time positions in 2013. In the same year, the industry had revenue of 14.1 billion DKK, costs of 12.4 billion DKK, earnings of 1.7 billion DKK, and net profits of 355 million DKK. The production by this industry was 449 thousand tonnes in 2015, of which 58 thousand tonnes were by herring and mackerel companies and 279 thousand tonnes by fishmeal companies.

Consequences of Brexit for Danish fisheries

With this overall picture in mind, the analysis focuses on the vessels which may experience the largest consequences of Brexit, that is, vessels obtaining more than 15% of their landings value from the UK-EEZ. With focus on these vessels, the analysis considers 98% of Danish landings value and weight from UK-EEZ. Based on the landing and cost information for the 15%-vessels, an economic analysis has been undertaken in order to show the effects for the Danish fishing fleet following Brexit. The analysis is data demanding, and various assumptions have therefore been set up in order to define the possible effects following different scenarios. In total, four overall scenarios have been investigated:

- 1) The negotiations end up with unchanged access to the UK-EEZ, i.e. a continuation of the current CFP,
- 2) All Danish (and other EU) vessels are excluded from fishing in the UK-EEZ, without possibility to take some of the catches previously taken in UK-EEZ in the NEW-EU-EEZ after Brexit,

- 3) As in scenario 2, all Danish (and other EU) vessels are excluded from fishing in the purely UK-EEZ rectangles but the fishing activity taking place in the UK part of the divided ICES-statistical rectangles can take place in the NEW-EU-EEZ, assuming that this geographical move of fishing effort in itself does not imply additional costs,
- 4) Catches taken in UK-EEZ before Brexit can for the top-5 most important species to a varying degree be caught in the NEW-EU-EEZ, depending on historical catch patterns of the different species.

The analysis has been based on the years 2014, 2015 and 2016, and it shows what would potentially have happened if Brexit had been in place in those years. The analysis is thus a short run analysis, without taking for instance any capacity adjustments into consideration.

The results of these four scenarios are shown in Table IV.2 as an average of 2014-2016.

Table IV.2 Aggregated landings value, gross profit and net profit, average of 2014-16 (1,000 DKK) and %.

	Scenario 1	Scenario 2		Scenario 3		Scenario 4	
	Given the current CFP	No landings from UK-EEZ		Landings from shared ICES-squares between UK-EEZ and NEW-EU-EEZ		All landings of top 5 species transferred from UK-EEZ to NEW-EU-EEZ, if possible	
Landings value	1,404,240	601,258	-57%	701,800	-50%	772,963	-45%
Gross profit	956,039	243,502	-75%	328,175	-66%	386,711	-60%
Net profit	699,750	127,063	-82%	192,546	-72%	238,824	-66%

Source: Own calculations

The overall picture is that the economic consequences for all fleets in all scenarios are severe. Unless the current CFP continues, Brexit will lead to a significant decline in landing values, gross profit, and net profit for the fleets involved. Despite the fact that gross profit and net profit for most fleets are still positive, the situation will require an adaptation in the number of vessels to adjust to the changes in fishing opportunities due to significant fixed costs in the fisheries, if one of these scenarios becomes the outcome of the negotiations.

It must be noted that the scenarios are formulated within the current framework for the Danish fishery. The Danish vessels might change behaviour in a way, which has not been foreseen in the analysis, or other fishing opportunities might become possible, for instance in the Norwegian zone. However, the analysed scenarios are useful to set the scene, and if the negotiations result in improvements compared to this, the negative economic consequences of Brexit will, of course, consequently be reduced.

Furthermore, the analysis has not considered any price effects following any change in trade agreements and consequences in trade patterns between the EU and UK. Analyses of such outcomes are beyond the scope of this report. However, given that fish prices in Denmark are mainly determined by world prices, no major price effects can be expected of Brexit.

Looking at the Danish harbours and their landings from the 15%-vessels, they primarily locate and land their fish in the harbours on the west coast of Northern Jutland. Skagen receives mostly herring and some reduction species, Hirtshals mostly receives herring and mackerel, while Thyborøn receives reduction species and some amounts of herring and some landings of demersal species. Hanstholm mostly receives demersal species. Some of the landings from these vessels take place in the UK, where Lerwick and Peterhead are the most important harbours. It is mostly mackerel and herring being landed in the UK harbours, but these landings are relatively small compared to the overall landings by the vessels.

Given the results from the analysed scenarios, Brexit can potentially lead to significantly reduced supplies of especially mackerel, herring and various species for reduction, and this can have an effect on the economic situation for the processing industry. A modelling framework for undertaking a detailed economic analysis of the processing industry is not available. If it is not possible to find substitutions for the supplies from the Danish fishery, production capacity and thus the related employment will most likely have to be adapted to this new situation.

For instance, UK vessels could potentially start to catch increased amounts of the reduction species or pelagic consumption species, if they are not caught by the Danish vessels, and these landings could be used in the Danish processing industry, if the UK vessels are allowed to land in Danish harbours. However, if the access to the landings from the UK vessels does not become possible, the Danish processing industry would require other suppliers of fish in order to continue the current level of production. The possibilities for this and the derived effects thereof have not been investigated.

The potentially reduced activity for the Danish fishing fleet in primarily the Northern part of western Jutland will also influence the onshore service industry, which delivers maintenance and supplies for the vessels and the crew. However, besides basic information about where the Danish fishing vessels have their homeport and most of their activity, it is not possible to do a more detailed analysis of the potential effects locally following each of the presented scenarios.
